Forage Research in Texas, 1993
Smutgrass Control

G. W. Evers and J. L. Gabrysch

Summary

Nine herbicides were evaluated for smutgrass (Sporobolus poiretii [R.S.] Hitchc.) control on clay soils at the Anson Research Station in southeast Texas. Dowpon (dalapon), Velpar (hexazinone), and Fusilade (fluazifop) were the most effective on smutgrass. Velpar is the only herbicide cleared for weed control in pastures at 0.69 to 1.12 lb ai/acre. The 1-lb rate was effective for smutgrass on clay soil at Anson, but the 0.5-lb rate resulted in only 40% control. Activity of Velpar at rates less than 1 lb/acre depends on soil moisture and time of application. Common bermudagrass (Cynodon dactylon (L.) Pers.), but not dallisgrass (Paspalum dilatatum Poir.) and bahiagrass (Paspalum notatum Flugge), was also injured by the recommended rates of Velpar.

Introduction

Smutgrass is a perennial bunch-type grass that is named for the black fungus (Helminthosporium ravenelii), which often attacks the seedhead and at times is found in patches on the leaves. Seed is spread by livestock, water, and wind and have been reported to remain viable for 2 or more years. Each plant produces more than 45,000 seed (Currey et al. 1973). More than 90% of the seed are hard, which allows unharm passage through cattle when eaten.

Smutgrass is a problem in both improved and native pastures in the southeastern United States. In Texas alone, 16 million acres are infected, most being in the eastern third of the state, particularly along the Gulf Coast (Meyer and Baur 1979). Cattle graze smutgrass during the winter and early spring, when other forages are not available (Durham and Kothmann 1977). Green, immature growth is of moderate quality, but fiber increases and protein and quality decrease with maturity. Livestock by-pass smutgrass when other forages become available in the spring. High production of hard seed and avoidance by livestock account for the spread and increase of smutgrass in pastures.

Dowpon (dalapon) was cleared for smutgrass control and was used successfully in conjunction with a winter pasture overseeding program (Riewe et al. 1975). However, the dalapon registration label was not renewed in the mid-1980’s. Numerous studies have evaluated other herbicides for controlling smutgrass (Teem et al. 1978, Meyer and Baur 1979). Velpar (hexazinone) provided good smutgrass control at 1 to 2 lb ai/acre and limited control at 0.5 to 0.75 lb ai/acre. The federal label was expanded in 1993 for smutgrass control in pastures.

Velpar and other herbicides were evaluated for smutgrass control at the Anson Research Station in the autumn of 1988 and 1989. Visual injury ratings were also made on common bermudagrass, dallisgrass, and bahiagrass in the 1989 study.

Procedure

1988 Study. The test site was a native pasture with a 70% smutgrass infestation on a Lake Charles clay at the Anson Research Station. The area was mowed about 1 month before treatment, so smutgrass plants were actively growing when herbicides were applied. Plots were 6 by 15 ft in a complete randomized block design with four replications. Herbicide treatments were applied 14 Oct. 1988 in 16.5 gal water/acre at 30 psi. No surfactants or additives were used. Soil moisture was good at the time of herbicide application but became low until December. Visual estimates of smutgrass control were made 16 May 1989.

Keywords: smutgrass / Sporobolus poiretii.
1989 Study. The test site was a 2-acre pasture at the Angleton Research Station consisting of smutgrass, common bermudagrass, dallisgrass, and bahiagrass. The area had been grazed by dry cows until 1 week before herbicides were applied. Plot size was 6 by 15 ft in a complete randomized block with four replications. Herbicide treatments were three rates of Velpar with 1 qt of nonphytotoxic petroleum oil\(^2\), one rate without petroleum oil, three rates of fusilade with petroleum oil, and one rate of Ally with a nonionic surfactant\(^3\) (0.25% v/v). Herbicides were applied in 16.5 gal water/acre at 30 psi on 7 Sept. 1989. Soil moisture was moderate; 0.75 in. of rain fell 2 days before herbicide application, but no significant rainfall occurred until November. Visual injury ratings were made 18 Sept. 1989, 11 days after herbicide application. Plant recovery was assessed again 19 Apr. 1990. Statistical analysis was not performed because botanical composition varied from plot to plot so that a plant species may not have been present in each replication of a treatment.

Results

Smutgrass control ranged from 0 to 100% in the 1988 study (Table 1). Dowpon, Fusilade, and the 2-lb rate of Velpar were the most effective (> 90% control). Oust and the high rate of Roundup had moderate activity, while Touchdown, Attrex, and Ally had poor activity against smutgrass. Velpar and Fusilade were evaluated in 1989 because they demonstrated the best smutgrass control the first year. An Ally treatment was repeated also. All Velpar treatments turned smutgrass brown, resulting in 100% injury rating at 11 days after application (Table 2). Common bermudagrass also became brown except at the low Velpar rate, which caused 70% injury. Dallisgrass and bahiagrass had ≤10% plant injury from Velpar treatments. Fusilade activity was slow because of the poor moisture conditions after herbicide application. Ally had very little effect on any of the grasses in 1989. A visual appraisal on 19 Apr. 1990 estimated smutgrass control at 40, 80, and 90% for 0.5, 1.0, and 2.0 lb ai/acre, respectively, of Velpar when applied with oil (data not shown). The 1-lb rate without crop oil was 65%. The other treatments had less than 40% smutgrass control.

Discussion

Dowpon was the most effective herbicide in controlling smutgrass but is no longer on the market. Velpar did a good job of controlling smutgrass at 1 lb ai/acre with 1 qt/acre of oil. Success with lower rates depends on good soil moisture for active plant growth to enhance Velpar uptake, time of application, and plant species present.

\(^i\)Petroleum oil (Agridex), 1 qt/acre.
\(^i\)Nonionic surfactant (X-77) 0.25% w/v.

The use of an additive such as petroleum oil. Experience of these authors and others (Meyer and Baur 1979, Riewe et al. 1975, Teem et al. 1978) is that herbicides are more effective on smutgrass when applied in September and October. It is believed that shorter days and/or cooler temperatures increase translocation to the root system, which enhances herbicide activity (Riewe et al. 1975). Pastures sprayed with Velpar cannot be grazed or harvested for hay within 60 days after application. Velpar at recommended rates of 0.5 to 1.0 lb ai/acre did injure common bermudagrass. Fusilade has some activity on smutgrass, but the interaction of rate, soil moisture, and time of year needs further investigation.
